

KeraNova Planned Tables and Figures

Committee output shells

KeraNova Research Team | Version 1.0 | 1 October 2026

1 How to use these shells

Replace each [pending] field only with a verified output from the locked analysis and its saved denominator. A shell is not a results table. Current endpoint/identifier deficiencies prevent the primary model: display not run — data readiness unmet in the submission rather than fabricated metrics. Raw extract counts must never be labelled the final eligible cohort.

Report eye counts and unique patient counts together. Continuous values use n, mean (SD) and median [IQR]; categories use n/N (%). Specify outcome availability, units and paired-change n. Unknown is separate from no/zero. The templates below correspond to the methodology and statistical plan.

Abbreviations: CDVA, corrected distance visual acuity; UDVA, uncorrected distance visual acuity; ACXL, accelerated corneal cross-linking; TG-PRK, topography-guided photorefractive keratectomy; TCT, thinnest corneal thickness; D, dioptres; MAE, mean absolute error; RMSE, root mean squared error; CI, confidence interval.
